1 General Safety Instructions

All pressure connections may only be opened after the system is without pressure!

Warning

Observe the national regulations about safety and accident prevention, as well as the safety instructions in this operating manual when operating the pressure transmitter.

Warning

Any operation not described in the following instructions must not be carried out.

Warning

If a failure cannot be repaired, the transmitter must be switched off. The operator must then make sure that it is only switched on again after the failure has been repaired.

Attention

Prior to installing, starting and operating a pressure measuring instrument, the user must ensure that the appropriate instrument has been selected with regard to scale range and performance and that the wetted parts material is suitable for the specific measuring conditions of the respective application.

Serious injuries and/or damage can occur should the relevant regulations not be observed.

Warning

Dangerous pressure media such as oxygen, acetylene, flammable gases or liquids and toxic gases or liquids as well as instruments for refrigeration plants or compressors etc. require attention above the standard regulations. Here the specific safety codes or regulations must be considered.

Warning

Remaining pressure medium contained in the pressure element may be hazardous or toxic. This should be considered when handling and storing the removed pressure measuring instrument.

Warning

Repairs should only be carried out by the manufacturer. All other repairs or modifications of the transmitter are unauthorized.

Attention

Other important safety guidelines can be found in the different sections of this instruction manual.
2 Product Description

The UniTrans pressure transmitter can be used in level control applications as well as for pressure measurement applications in process industry. A variety of process connections, measurement ranges, main boards and display options result in a product for a wide range of applications.

2.1 Construction

The UniTrans consists of a pressure sensor, a control interface unit and a housing cover with optional display. Due to this modular design, different transmitter versions can be mounted (see “Model Key” on page 79).

2.1.1 Pressure Transducer

The pressure transducer has a piezo-resistive or thinfilm measurement cell depending on the pressure range. The sensors are temperature compensated, and have a hermetically welded membrane which is "helium" leak-tested. The pressure transducers do not have internal sealing elements.

Pressure transducers further distinguish themselves from one another based on their pressure ranges and the different materials of wetted parts. Different process connections can be selected to serve a wide range of applications.

Never exceed the overpressure limit of the respective pressure transducer.

Attention
2.1.2 Processing Unit

The processing unit, which is integrated in the housing contains the terminal compartment and the keypad used for programming the transmitter. The four keys must be activated (unlocked) before use. During normal operation the keypad is locked to protect data and functions previously entered. The keypad is automatically locked when no key is hit for 10 minutes. The processing unit converts the digitized signal from the measuring unit into a standard 4...20 mA current signal.

2.1.3 Display Unit

The indicator has four digits (7-segment display) + symbols. Below it, line 1 (16-segment display) is used to display error codes and the signal’s unit of measure. The unit of measure can be selected by the operator. Measurements over 9999 can not be correctly displayed. Please note this when choosing the unit (e.g. 9999 Pascal = 0,09999 bar). Additional information is displayed in lines 2 and 3 (16-segment display). The operator can enter commands in the programming mode on the display unit by means of menu guided, clear-text prompts.
Transmitters with displays offer a larger number of programming and processing options. These options include alarm status, damping, signal inversion, tank linearization and diagnostic messages.

*Display units can be easily upgraded (see chapter 4.2).*

### 2.2 Function

The mode of operation for signal conversion works in the same way for all versions. The pressure transducer converts the existing pressure into an electrical signal. Microelectronics further process the input signal and produce a proportional 4-20 mA standard signal.

The display-version allows programming (parameterization) and the display of extended functions such as inversion, damping, alarm status and linearization.

#### 2.2.1 Functions of Transmitters without Displays

- Calibration of zero and span under pressure (see 5.3)
- Calibration of zero and span without pressure (dry adjustment) (see 5.4)
- Setting the dampening / integrating the output signal 0-40 s (see 5.5)
- Reset to manufacturer’s default values (see 5.6)
- Mounting correction of the sensor (beginning with software version 1.05) (see section 5.4.3)

#### 2.2.2 Functions of Transmitters with Displays

- Settable units of measurement  (mbar, bar, psi, mA, %, m, mm WS) (see 6.5.1)
- Temperature and Min/Max values shown in display (see 6.5.1)
- Nominal pressure range of the sensor shown in display (see 6.5.1)
- Zero and span calibration (with/without pressure) (see 6.5.2)
- Setting of damping / integration of output signal 0-40 s (see 6.5.3)
- Inversion of the output current signal (see 6.5.3)
- Setting the output current value in case of alarm  (3.6 mA or 21 mA) (see 6.5.3)
- Setting the limits of the output signal (see 6.5.3)
- Offset of the output signal (see 6.5.3)
- Mounting correction of the sensor
- Measuring circuit test function (see 6.5.4)
- Reset functions (see 6.5.4)
- Password activation (see 6.5.4)
- Selecting the language of the display (see 6.5.5)
- Entering of a table function for the linearization of the output signal (see 6.5.6)
- Entering the medium density (see 6.5.6)
2.3 Installation Examples

The UniTrans is primarily used to monitor the pressure in pipes, technical equipment and tanks. Depending on the pressure range pressures between 20 mbar up to 1000 bar can be measured. The pressure is measured using absolute (against a vacuum) or relative (against external or air pressure) measurement depending on the type of sensor selected.

The UniTrans is also used for hydrostatic pressure measurement within liquid filled pipes and containers.

**Process Pressure Measurement:**
*Used to measure pressure of liquids or gases in pipelines.*

**Process Pressure Measurement:**
*Used to measure container pressure.*

**Process Pressure Measurement:**
*Installed behind feed pumps for process control or monitoring of pump functions.*

**Process Pressure Measurement:**
*Installed in front of and behind the filter. Uses the pressure differential for monitoring the function or accumulation of dirt in the filter. Both output signals are processed by a PLC or signal converter.*
Universal Pressure Transmitter UniTrans
Product Description

Level Control:
Externally mounted
(with front flat diaphragm)

Combined pressure and head pressure are measured by two externally mounted pressure transducers. The two signals are analyzed and the differential is calculated by a PLC or suitable signal converter.

4 Installation

The device should be installed/operated in accordance with the regulations of ElexV, the Device Safety Regulation, this operating manual and generally recognized industry standards.

4.1 Pressure Transmitter Installation

\[\text{Attention}\]

The pressure transmitter’s diaphragm should not come into contact with hard or sharp objects.

Installation Using a Weld-on Adapter:
- Insert a filler piece (a pressure transmitter dummy) into the weld-on adapter.
- Weld the adapter into the container/pipe wall (section-weld process).
- Remove the filler piece.
- Install the pressure transmitter in the weld-on adapter.

4.2 Display Unit Upgrades

The display unit can be easily upgraded at any time.
- Remove the housing cover and the supporting string.
- Attach the display unit’s supporting string to the same place.
- Plug the display unit’s connector into the appropriate jack.
  The display unit can be mounted at 90° angles.
- Fasten the display unit with screws.

\[\text{Attention}\]

When installing the display unit, make sure that the connection cable and the supporting string are not kinked or pinched.
All functions are programmable once the pressure transmitter has been upgraded with a display unit. The adjusted parameters are stored after the display unit is removed.

The display unit can be rotated in 300°, so that it can be read under various installation conditions. The housing cover with built-in display can be fastened to the housing at all four side positions.

4.3 Housing Reconfiguration

Rotate the housing of the display unit in order to be able to read the display from above when the pressure transmitter is installed in an upright position.

- Loosen the 4 internal hexagonal screws.
- Lightly lift off the housing with the display unit.
- Carefully turn the housing by 180°.
- Re-tighten the screws.

Attention

When tightening the 4 hollow screws, make sure that they are adequately and securely seated in order to ensure that the transmitter is properly sealed.
4.4 Electrical Connection

Please observe local installation regulations (Germany: VDE-Standard). The terminal voltage should not exceed 36 V.

Attention

The supply voltage is between 12 and 36 V DC. The power supply and the output signal are transmitted via a two-wire cable (max. 12 mm outer diameter, max. 14 AWG) and connected in accordance with the pin configuration.

Supply voltage can be supplied by a power unit, a transmitter power supply or by means of a PLC connection.

It is suggested to use a model with integrated lightning protection for preventing damage due to voltage peaks.
Terminal Configuration

- Ground
- L- supply minus (to connect the negative signal line)
- L+ supply plus (to connect the positive signal line)
- I Test circuit; connect the ampere meter between terminals L+ and I

The unit must be properly grounded in order to guarantee EMC resistance.

4.5 Pressure Compensation when using a Relative Pressure Sensor

A Goretex diaphragm is used to compensate for the atmospheric pressure under the IP 65 Protection Method.

A special cable with capillaries for relative pressurization is used for Ingress Protection IP 67.
5 Operation of Transmitters without Display

5.1 Preparation

This unit can be programmed before or after installation.

- Connect an ampere meter to the device’s output (between terminals I and L+).
- Note that after each action, a brief oscillation/deflection of 20 mA occurs (verification of a successful action).

The following functions can be programmed without a display unit:

- Zero point adjustment with a full or empty container (with/without pressure)
- Span adjustment with a full or empty container (with/without pressure)
- Integration time
- Reset to manufacturer’s defaults

An error signal is caused by a current surge (21 mA or 3.6 mA; 5 sec) when the zero point or span setting fall outside of the sensor’s nominal pressure range during adjustments with existing pressure. No values are stored. The keypad becomes inactive after 10 min. of disuse. All settings will default to previously stored values. Only settings that have been confirmed with the "OK" function are stored.

</tbody>
</table>
5.3 Calibration with Pressure

5.3.1 Zero Point Calibration

Make sure that the pressure to be used as the zero point (P 0 %), is present at the transmitter diaphragm before calibration.

A change in the zero point has no effect on the calibrated span. However, if the span end-point is higher than the peak value of the sensor’s nominal pressure range, then span end-point is fixed at this peak value and the span is reduced accordingly.

5.3.2 Span Calibration

Calibration of the measurement range (span).

Make sure that the pressure to be used as the span end-point (P 100 %) is present at the transmitter diaphragm. The measuring range between zero and end value of span is saved as span.

A change in the span setting has no effect on the zero point. The zero point and span end-point must fall within the sensor’s nominal pressure range.

A mounting correction must not be carried out when making an adjustment with pressure (wet adjustment). Otherwise, the mounting correction must be carried out before saving the zero point and the end value of span.
5.4 Calibration without Pressure

Determine the current reference values for the zero point and the span to be entered in the transmitter before calibration. This is done as follows:

5.4.1 Zero Point Calibration

- Determine the hydrostatic pressure of the liquid’s surface that meets the zero point.
- Adjust this pressure in proportion to the sensor’s nominal pressure range.
- Multiply this proportion by 16 mA and add 4 mA to the result.

This produces the calculated current (value $I_{\text{calc}}$), which is entered in the transmitter and used to program the zero point (0%).

Example:

A pressure transducer with 0 ... 400 mbar (nominal pressure) needs to be programmed. The liquid’s surface (with a density of 1) is 1 m above the diaphragm at the zero point producing a pressure of 100 mbar.

$$I_{\text{calc}} = \frac{\text{Zero point pressure (0%)} \times 100 \text{ mbar}}{\text{Sensors nominal pressure 400 mbar}} \times 16 \text{ mA} + 4 \text{ mA} = 8 \text{ mA}$$

This means that the device’s current value must be set to 8 mA when performing a dry (empty) calibration.

5.4.2 Span Calibration

- Determine the hydrostatic pressure of the liquid’s surface, which corresponds to the span end-point.
- Calculate the difference of the pressure value between span end-point and zero point and divide this difference by the nominal pressure range of the sensor.
- Multiply this proportion by 16 mA and add 4 mA to the result.

This produces the calculated current (value $I_{\text{calc}}$), which is entered in the transmitter and used to program the span end-point (100%).

The measurement range between zero point and span end-point will be stored as span.
Example:
A pressure transmitter with 0 ... 400 mbar (nominal pressure) is to be programmed.
The liquid’s surface (with a density of 1) is 1 m above the diaphragm at the zero point.
The maximum (span end-point) should be 3 m. The measuring range (span) is 200 mbar.

\[ I_{\text{calc}} = \frac{\text{pressure difference (span)} \times (300 \text{ mbar} - 100 \text{ mbar})}{\text{Sensors nominal pressure} \times 400 \text{ mbar}} \times 16 \text{ mA} + 4 \text{ mA} = 12 \text{ mA} \]

This means that the output must be set to 12 mA during programming.

A change in the zero point has no effect on the adjusted span.
However, if the span end-point is higher than the peak value of the transmitter’s nominal pressure range, then the span end-point is fixed at this peak value and the span is reduced accordingly.
A change in the span setting has no effect on the zero point. The zero point and span end-point must fall within the transmitter’s nominal pressure range.

A test / correction of the zero point is suggested after adjusting the span in order to maintain optimum accuracy.
A mounting correction should be carried out before or after making an adjustment without pressure (dry adjustment) (see 5.4.3). The transmitter must therefore be placed in the reference position for the measurement (installation site) without pressure on the diaphragm.

5.4.3 Mounting correction of the sensor

The position of the measuring cell is adjusted by simultaneously pressing (2 sec.) the "zero" and "esc" buttons.
5.5 Integration Time (Damping) Adjustment

The following integration time settings can be used: 0, 1, 5, 20 and 40 s.

The sensor’s measured values can then be averaged using the adjusted integration time.

5.6 Reset to Default

All default data settings are restored by simultaneously pressing the "zero", "esc" and the "ok" buttons for 2 seconds (see chapter 6.4).

Calibrated special measurement ranges i.e. 4 bar on a 6 bar transmitter can be adjusted by factory pre-setting. A reset to default will reset the sensor back to its nominal range (i.e. 6 bar). The factory pre-setting gets lost.
6 Operation of Transmitters with Display

6.1 The Display

In order to program the device, remove the display with a screwdriver and re-attach it to the housing as shown in the diagram below.

6.3 The Programming Mode

The transmitter can be programmed before or after installation.

The keypad is activated and the device can be programmed by simultaneously pressing the "esc" and "ok" keys (for 2 sec.). This method is used to access the main menus. Each main menu has one or more sub-menus and each sub-menu, may have its own sub-menus.

The keypad becomes inactive after 10 min. of disuse. All settings will default to previously stored values. Only settings that have been confirmed with the "OK" function are stored.

A change in the starting measurement (zero point) has no effect on the measurement span. Likewise, a change in the span has no effect on the starting measurement.

An error signal occurs when the zero point or span settings fall outside of the sensor’s nominal pressure range during calibration with pressure. Nothing is saved.
### 6.4 Default Data (factory settings)

*Calibrated special measurement ranges i.e. 4 bar on a 6 bar transmitter can be adjusted by factory pre-setting. A reset to default will reset the sensor back to its nominal range (i.e. 6 bar). The factory pre-setting gets lost.*

6.5.2 Main Menu: Calibration of zero and span

A single pressure value is set for the zero point or the span end-point within the sensor’s nominal pressure range, and assigned to the associated output current signal when making adjustments with existing pressure. An error signal occurs when the existing pressure lies outside of the sensor’s nominal pressure range. The value is not saved in this case.

A mounting correction should be performed before or after making an adjustment without pressure (dry adjustment) (see 6.5.6). The sensor must therefore be placed in the reference position for the measurement (installation site) without pressure on the diaphragm.

A mounting correction is unnecessary when making an adjustment with pressure (wet adjustment). Otherwise, the mounting correction must be performed before saving the zero point and span end-point.

A test / correction of the zero point is suggested after adjusting the span in order to maintain optimum accuracy.
6.5.3 Main Menu: Output

- **Damping**
  - 40 s active
  - 20 s active
  - 5 s active
  - 1 s active

- **Output Inversion**
  - Off
  - On

- **Alarm/Error**
  - Alarm at 3.6 mA (downscale)
  - Alarm at 21 mA (upscale)

- **Limits**
  - Measured value runs between 3.8 mA and 20.5 mA. The current holds at the limit when the sensing range is exceeded.
  - The current runs between 4 and 20 mA. Alarm condition when limits are reached; it is necessary to restart device by using reset or by shutting down power (see 8.5.6).
  - The output current is combined with an assigned offset, which can have a maximum of ±0.4 mA.

Query routine for additional safety.
6.5.4 Main Menu: Evaluation

Enter height values, which are each assigned a volumetric value of measure for tank linearization. The linearization and the assignment of the 4 ... 20 mA output signal are converted into tank volumes using this value pair.

When the evaluations function is activated the Turn down becomes inactive.
Please check the following if "Wrong Entry" appears in the Evaluation menu:

- whether or not more than 32 value pairs are entered in the table for tank linearization (please note: P0 and P31 are fixed at 0% and 100% respectively)
- whether or not an existing height value was tried to be stored again

**Example:**

Level 100 %: 4000 mm
Density: 1 g/cm³
Density correction: 0.9 g/cm³
Span end point: \[
\frac{4000 \text{ mm} \cdot 1 \text{ g/cm}^3}{0.9 \text{ g/cm}^3} = 4444 \text{ mm}
\]

The span (end-point) must be re-calibrated (with or without pressure) to 4000 mm in order to prevent a 4000 mm level tank from being overfilled.

**Important**

A change or correction in the density causes a change in the span end-point’s unit of measure (mm, m, inch, feet). The span end-point must be re-calibrated when changing the medium to be measured (due to a change in density).

### 6.5.5 Main Menu: Language

```
<table>
<thead>

6.5.6 Main Menu: Service

- **Main Menu Service**: 
  - **Service Functions**: 
    - Mounting correction is performed; sensor must be correctly positioned and mounted without pressure.
  - **Mounting Correction**
  - **Service Loop Test**: The set current value is used as the test signal until the "Esc" button is pressed.
  - **Service Device Data**: 
    - **Service Timer**: Total number of operating hours.
    - **Service Reset**: 
      - **Reset Timer**: Number of hours since the last Reset.
      - **Reset Min/Max Values**: Min/Max values are reset.
      - **Reset All**: All values are reset to the factory setting (see 6.4).
      - **Reset Alarm**: Reset the alarm after exceeding the 4/20 mA limit, necessary when setting fixed limits 4/20 mA FIX (see 6.5.3).
  - **Service Password**: A digital value between 0000 and 9999 is set as the password.
7 Diagnostics and Service

If a failure cannot be repaired, the transmitter must be switched off. The operator then must make sure, that it is only switched on again after the failure has been repaired.

Repairs should only be carried out by the manufacturer. All other repairs or modifications are unauthorized.

The following error messages can appear on devices with displays (see chapter 2.1.3):

<table>

</tbody>
</table>

8 Disposal

Please observe local guidelines and regulations when disposing of transmitters that are no longer serviceable.

Please turn any recycleable components in to the appropriate local organizations.

9.3 Warranty Conditions

The pressure transmitter has a 24 month warranty in accordance with the WIKA General Terms of Delivery.

Attention: Repairs may only be carried out by the manufacturer. All other repairs and device modifications are unauthorized and will void the warranty.

9.4 Glossary

- **Adjustment**: Allocation of the signal output range (4 ... 20 mA) to the desired pressure measurement range or level measurement range.
- **Integration**: Also damping: timely communication of the measurement signal; rise time of the current output signal after a signal surge.
- **Inversion**: Conversion of the output signal from 4 ... 20 mA to 20 ... 4 mA.
- **Nom. pressure range**: The operating pressure range for which the sensor was designed.
- **Zero point**: Start of the pressure measurement range.
- **Parameterization**: Also configuration: programming of the relevant parameters and the pressure measurement range specific to the application and measurement location.
- **Span**: The programmed pressure measurement range.
- **Span end point**: The highest pressure value of the programmed measurement span (end-point of the span).
- **Tank linearization**: Determination of approximate volume/pressure ratio values with non-linear correlations based on varying container designs. For example, a non-linear correlation exists between the fill level and the volume in spherical containers. During linearization, the non-linear volume is assigned the 4 ... 20 mA output signal from a table of values (proximity process by means of up to 32 support points).
- **Defaults**: The sensor parameters are pre-programmed by the manufacturer.

9.5 Units of Pressure Measurement

- 1 atm (atmospheres) = 760 mm Hg = 760 Torr = 1.033 kp/cm² = 0.1013 MPa
- 1 Torr = 133.3 Pa
- 1 kp/mm² = 9.81 N/mm² = 9.81 MPa
- 1 bar = 0.1 MPa
- 1 mbar = 1 hPa (Hektopascal)
- 1 psi (pound per square inch) = 6.895 · 10³ Pa
- 1 bar = 33.5 feet of water
- 1 PA = 1.0 x 10⁻⁵ bar
- 1 mmHg = 1.333 mbar
